FAMILIES OF EXPLICIT ISOGENIES OF HYPERELLIPTIC JACOBIANS

BENJAMIN SMITH

Abstract. We construct three-dimensional families of hyperelliptic curves of genus 6, 12, and 14, two-dimensional families of hyperelliptic curves of genus 3, 6, 7, 10, 20, and 30, and one-dimensional families of hyperelliptic curves of genus 5, 10 and 15, all of which are equipped with an an explicit isogeny from their Jacobian to another hyperelliptic Jacobian. We show that the Jacobians are generically absolutely simple, and describe the kernels of the isogenies. The families are derived from Cassou–Noguès and Couveignes' explicit classification of pairs (f, g) of polynomials such that $f(x_1) - g(x_2)$ is reducible.

1. Introduction

In this article, we construct twelve explicit families of isogenies of hyperelliptic Jacobians. By explicit, we mean that we provide equations for hyperelliptic curves generating the domains and codomains of each isogeny, together with a correspondence on the curves realizing the isogeny as a map on divisor classes. Our main results are summarized by Theorem 1.1, which follows from the examples of §6. We also construct some families of Jacobians with explicit Real Multiplication, including and generalizing the families described by Tautz, Top, and Verberkmoes [26].

Theorem 1.1. *For each row of the following table, there exists an n-dimensional family of explicit isogenies of Jacobians of hyperelliptic curves of genus g over k, with kernel isomorphic to G (and hence splitting multiplication-by-m). The generic fibre of each family is an isogeny of absolutely simple Jacobians.*

g	n	$[m]$	G	k
3	2	[2]	$(\mathbb{Z}/2\mathbb{Z})^3$	$\mathbb{Q}(\sqrt{-7})$
5	1	[3]	$(\mathbb{Z}/3\mathbb{Z})^5$	$\mathbb{Q}(\sqrt{-11})$
6	3	[2]	$(\mathbb{Z}/2\mathbb{Z})^6$	$\mathbb{Q}(\sqrt{-7})$
6	2	[3]	$(\mathbb{Z}/3\mathbb{Z})^6$	$\mathbb{Q}(\sqrt{-3\sqrt{13}+1})$
7	2	[4]	$(\mathbb{Z}/4\mathbb{Z})^4 \times (\mathbb{Z}/2\mathbb{Z})^6$	$\mathbb{Q}(\sqrt{-15})$
10	2	[3]	$(\mathbb{Z}/3\mathbb{Z})^{10}$	$\mathbb{Q}(\sqrt{-11})$
10	1	[4]	$(\mathbb{Z}/4\mathbb{Z})^9 \times (\mathbb{Z}/2\mathbb{Z})^2$	$\mathbb{Q}(\sqrt{-7})$
12	3	[3]	$(\mathbb{Z}/3\mathbb{Z})^{12}$	$\mathbb{Q}(\sqrt{-3\sqrt{13}+1})$
14	3	[4]	$(\mathbb{Z}/4\mathbb{Z})^9 \times (\mathbb{Z}/2\mathbb{Z})^{10}$	$\mathbb{Q}(\sqrt{-15})$
15	1	[8]	$(\mathbb{Z}/8\mathbb{Z})^5 \times (\mathbb{Z}/4\mathbb{Z})^{10} \times (\mathbb{Z}/4\mathbb{Z})^{10}$	*Sextic CM-field (see Ex. 4.8)*
20	2	[4]	$(\mathbb{Z}/4\mathbb{Z})^{19} \times (\mathbb{Z}/2\mathbb{Z})^2$	$\mathbb{Q}(\sqrt{-7})$
30	2	[8]	$(\mathbb{Z}/8\mathbb{Z})^{11} \times (\mathbb{Z}/4\mathbb{Z})^{19} \times (\mathbb{Z}/4\mathbb{Z})^{19}$	*Sextic CM-field (see Ex. 4.8)*

Our families of isogenies are derived from the remarkable explicit classification of pairs of polynomials (f, g) such that $f(x_1) - g(x_2)$ is reducible due to Cassou–Nogùes and Couveignes [5], building upon the work of Fried [10, 11, 12], Feit [7, 8, 9], and others [4]. We associate a family of pairs of curves to every such pair (f, g), and a family of explicit homomorphisms (between the Jacobians of the curves of each pair) to each factor of $f(x_1) - g(x_2)$. We show that each homomorphism is in fact an isogeny of (generically) absolutely simple Jacobians, and compute the isomorphism type of the kernels. We also calculate the dimension of the image of each family in its appropriate moduli space.

Over the complex field, abelian varieties are complex tori, and we may construct isogenies by working with period matrices. Over arbitrary fields, these methods are not available to us; the only abelian varieties for which we have a convenient representation for explicit computation are Jacobians of curves, where we can use the standard isomorphism with the divisor class group. However, the Jacobians occupy a positive-codimension subspace of the moduli space of abelian varieties in dimension greater than three, so an isogeny with a Jacobian for a domain generally does not have another Jacobian for a codomain. For this reason, examples of explicit isogenies of higher-dimensional abelian varieties are particularly rare (setting aside endomorphisms such as integer multiplication and Frobenius). We note that recently, Mestre has described a $(g+1)$-dimensional family of $(\mathbb{Z}/2\mathbb{Z})^g$-isogenies of Jacobians of hyperelliptic curves of genus g for every $g \geq 1$ (see [21]). Our families of isogenies are defined over number fields, and provide a source of examples of explicit isogenies of high-dimensional abelian varieties over exact fields.

This work generalizes some results from the author's unpublished thesis [24, §6]. The subfamily at $s = 0$ of the isogeny in Example 6.1 and the fibre at $s = 0$ of the isogeny in Example 6.3 also appeared earlier in the thesis of Kux [18, §4.1]. The Real Multiplication families in Examples 5.2 and 5.3 appeared in the work of Tautz, Top, and Verberkmoes [26]. We assume some familiarity with the basic theory of curves and abelian varieties, referring the reader to Birkenhake and Lange [1], Hindry and Silverman [14, Part A], Milne [22], and Shimura [23] for further details.

Notation. Throughout this article, ζ_n denotes a primitive n^{th} root of unity in $\overline{\mathbb{Q}}$. If σ is an automorphism of a field k and $f(x) = \sum_i c_i x^i$ is a polynomial over k, then we write $f^\sigma(x)$ for the polynomial $\sum_i c_i^\sigma x^i$. If ϕ is an isogeny of abelian varieties with kernel isomorphic to a group G, then we say that ϕ is a G-isogeny.

Acknowledgements. The author is grateful to the mathematics departments of the University of Sydney and Royal Holloway, University of London, where parts of this work were carried out. This research was supported in part by EPSRC grant EP/C014839/1.

2. The basic construction

Suppose (f, g) is a pair of squarefree polynomials of degree at least 5 over k such that there exists a nontrivial factorization

$$f(x_1) - g(x_2) = A(x_1, x_2)B(x_1, x_2).$$

Given such a pair of polynomials, we define a pair (X, Y) of hyperelliptic curves by

$$X : y_1^2 = f(x_1) \quad \text{and} \quad Y : y_2^2 = g(x_2).$$

The factors A and B of $f(x_1) - g(x_2)$ define explicit homomorphisms from J_X to J_Y as follows: Let C be the correspondence on $X \times Y$ defined by

$$C := V(y_1 - y_2, A(x_1, x_2)) \subset X \times Y. \tag{1}$$

The natural projections of $X \times Y$ restrict to coverings $\pi_X : C \to X$ and $\pi_Y : C \to Y$. Composing the pullback $(\pi_X)^* : J_X \to J_C$ with the pushforward $(\pi_Y)_* : J_C \to J_Y$, we obtain a homomorphism

$$\phi := (\pi_Y)_* \circ (\pi_X)^* : J_X \longrightarrow J_Y; \tag{2}$$

we say ϕ is *induced* by C. The homomorphism ϕ is completely explicit: we can compute the image of a divisor class on X under ϕ by pulling back a representative divisor to C and then pushing the result forward onto Y.

If we replace A with B in (1), we obtain the homomorphism $-\phi$. Exchanging X and Y in (2), we obtain the Rosati dual homomorphism $\phi^\dagger : J_Y \to J_X$ (recall $\phi^\dagger = \lambda_X^{-1}\hat{\phi}\lambda_Y$, where $\hat{\phi} : \widehat{J}_Y \to \widehat{J}_X$ is the dual homomorphism and $\lambda_X : J_X \xrightarrow{\sim} \widehat{J}_X$ and $\lambda_Y : J_Y \xrightarrow{\sim} \widehat{J}_Y$ are the canonical principal polarizations).

If $A(x_1, x_2)$ divides $f(x_1) - g(x_2)$, then it also divides $F(f(x_1)) - F(g(x_2))$ for every polynomial F over k. Therefore, if we let $F = x^d + s_1x^{d-1} + \cdots + s_{d-1}x + s_d$ be the generic monic polynomial of degree d (where the s_i are free parameters), let Δ_f (resp. Δ_g) be the discriminant of $F(f(x))$ (resp. $F(g(x))$), and let T be the parameter space defined by

$$T := \operatorname{Spec}(k[s_1, \ldots, s_d]) \setminus (V(\Delta_f) \cup V(\Delta_g)),$$

then we obtain a d-parameter family $(\mathcal{X}, \mathcal{Y}) \to T$ of pairs of curves defined by

$$\mathcal{X} : y_1^2 = F(f(x_1)) = f(x_1)^d + s_1 f(x_1)^{d-1} + \cdots + s_{d-1}f(x_1) + s_d$$

and

$$\mathcal{Y} : y_2^2 = F(g(x_2)) = g(x_2)^d + s_1 g(x_2)^{d-1} + \cdots + s_{d-1}g(x_2) + s_d,$$

together with a family of homomorphisms $\phi : \mathcal{J}_\mathcal{X} \to \mathcal{J}_\mathcal{Y}$ induced by the correspondence

$$C = V(y_1 - y_2, A(x_1, x_2)) \subset \mathcal{X} \times_T \mathcal{Y}.$$

That is, for each P in T, if C_P, X_P, and Y_P are the fibres of C, $\mathcal{X}$, and $\mathcal{Y}$ over P, then C_P induces a homomorphism $\phi_P : J_{X_P} \to J_{Y_P}$.

If f and g are defined over a polynomial ring $k[t]$, then we can define $(d+1)$-parameter families of pairs of curves and homomorphisms, this time parameterised by $T = \operatorname{Spec}(k[t, s_1, \ldots, s_d]) \setminus (V(\Delta_f) \cup V(\Delta_g))$, in exactly the same way. Throughout this article we will use T to denote the parameter space of each of our families; the precise definition of T in each case will be clear from the context.

We will restrict our attention to the cases $d = \deg F = 1$ (the *linear construction*) and $d = \deg F = 2$ (the *quadratic construction*). For higher degrees d, the Jacobians of $\mathcal{X}$ and $\mathcal{Y}$ are reducible. Indeed, we have a covering $(x, y) \mapsto (f(x), y)$ from $\mathcal{X}$ to the curve $\mathcal{X}' : v^2 = F(u)$, so $\mathcal{J}_{\mathcal{X}'}$ is an isogeny factor of $\mathcal{J}_\mathcal{X}$ whenever $\mathcal{X}'$ has positive genus: that is, whenever $d > 2$. We aim to construct explicit isogenies of absolutely simple Jacobians, so we will leave aside $d > 2$.

Remark 2.1. Our constructions depend only on f and g, and generalize to variable-separated curves — that is, curves of the form $P(y) = f(x)$ where $\deg P > 2$. The analysis of the resulting homomorphisms is more detailed, however, and some of the methods we use in §3 do not readily extend to the separated-variable case. We will return to these constructions in future work.

3. DETERMINING KERNEL STRUCTURE

Suppose $\mathcal{X}$, $\mathcal{Y}$, and $\phi : \mathcal{J}_\mathcal{X} \to \mathcal{J}_\mathcal{Y}$ are defined as in the previous section. We want to determine whether ϕ is an isogeny, and if so to compute a group G isomorphic to its kernel. It suffices to consider the generic fibre $\phi : J_X \to J_Y$, which is defined over $\overline{\mathbb{Q}}(T)$, a field of characteristic zero.

The first step is to show that J_X is absolutely simple; then ϕ is an isogeny if and only if it is nonzero. Further, if ϕ is an isogeny and J_X is absolutely simple and $g_X = g_Y$ then J_Y must also be absolutely simple, and ϕ itself cannot arise from a product of isogenies of lower-dimensional abelian varieties. Since a reducible abelian variety cannot specialize to to an absolutely simple one, it is enough to exhibit a point P of the parameter space T such that the specialization J_P of $\mathcal{J}_\mathcal{X}$

at P is absolutely simple. In Examples 6.1 and 6.5, there will exist a convenient choice of P allowing us to deduce the simplicity of J_P from CM-theory. For the other examples, we will use the fact that J_P is defined over a number field K, and exhibit a prime $\mathfrak{p}$ of K such that the (good) reduction $\overline{J_P}$ of J_P at $\mathfrak{p}$ is absolutely simple; the absolute simplicity of J_P, and thus the absolute simplicity of J_X, then follows from [6, Lemma 6].

To show that $\overline{J_P}$ is absolutely simple, we compute its Weil polynomial χ (that is, the characteristic polynomial of its Frobenius endomorphism) using Kedlaya's algorithm [16], which is implemented in Magma [13, 2]. (For this to be practical the norm of $\mathfrak{p}$ must be a power of a small prime, especially for the higher-genus families.) If χ is irreducible, then $\overline{J_P}$ is simple. To determine whether $\overline{J_P}$ is *absolutely* simple, we apply the criterion appearing in [15]:

Lemma 3.1 (Howe and Zhu)**.** *Suppose A is a simple abelian variety over a finite field, and let χ be its (irreducible) Weil polynomial. Let π be an element of $\overline{\mathbb{Q}}$ satisfying $\chi(\pi) = 0$. Let D be the set of integers $d > 1$ such that either*

1. *$\chi(x)$ lies in $\mathbb{Z}[x^d]$, or*
2. *$[\mathbb{Q}(\pi) : \mathbb{Q}(\pi^d)] > 1$ and $\mathbb{Q}(\pi) = \mathbb{Q}(\pi^d, \zeta_d)$.*

If D is empty, then A is absolutely simple.

Proof. See [15, Proposition 3]. Note that $D \subset \{d \in \mathbb{Z}_{>0} : \varphi(d) \mid 2\dim A\}$, so this criterion can be efficiently checked. ☐

We will be handling some large Weil polynomials. To save space, we will use the following, more compact representation.

Definition 3.1. Suppose A is a g-dimensional abelian variety over $\mathbb{F}_q$ with Weil polynomial χ. We define the *Weil coefficients* of A to be the integers $w_1, \ldots, w_g$ such that

$$\chi(x) = x^{2g} + w_1 t^{2g-1} + \cdots + w_g x^g + w_{g-1} q x^{g-1} + \cdots + w_1 q^{g-1} x + q^g.$$

Recall that $\phi^\dagger \circ \phi$ is an endomorphism of $\mathcal{J}_{\mathcal{X}}$; if ϕ is an isogeny of absolutely simple Jacobians, then $\phi^\dagger \circ \phi = [m]_{\mathcal{J}_{\mathcal{X}}}$ for some nonzero integer m. Conversely, if $\phi^\dagger \circ \phi = [m]_{\mathcal{J}_{\mathcal{X}}}$ for some m, then ϕ is an isogeny and $\ker \phi \subset \mathcal{J}_{\mathcal{X}}[m]$. Since ϕ is an isogeny of Jacobians (thus respecting the canonical polarizations), its kernel must be a maximal isotropic subgroup of $\mathcal{J}_{\mathcal{X}}[m]$ with respect to the m-Weil pairing; the nondegeneracy of the Weil pairing then gives the following elementary result.

Lemma 3.2. *If $\phi^\dagger \circ \phi = [m]_{\mathcal{J}_{\mathcal{X}}}$ for some positive integer m, then ϕ is a G-isogeny for some subgroup G of $(\mathbb{Z}/m\mathbb{Z})^{2g_{\mathcal{X}}}$ such that $G \cong (\mathbb{Z}/m\mathbb{Z})^{2g_{\mathcal{X}}}/G$. Further, if m is squarefree, then $G \cong (\mathbb{Z}/m\mathbb{Z})^{g_{\mathcal{X}}}$.*

Let $K = \overline{\mathbb{Q}}(T)$ denote the base field of the generic fibre, and let $\Omega(X)$ and $\Omega(Y)$ denote the K-vector spaces of regular differentials on X and Y, respectively. We have the well-known representation

$$D_{X,Y}(\cdot) : \mathrm{Hom}(J_X, J_Y) \longrightarrow \mathrm{Hom}(\Omega(X), \Omega(Y)),$$

sending a homomorphism to the induced map on differentials (see Shimura [23, §2.9] for details). This representation is faithful in characteristic zero, and it respects composition: if $\phi : J_X \to J_Y$ and $\psi : J_Y \to J_Z$ are homomorphisms, then

$$D_{X,Z}(\psi \circ \phi) = D_{X,Y}(\phi) D_{Y,Z}(\psi).$$

In particular, when $J_X \cong J_Y$ we obtain a representation of rings

$$D_X(\cdot) : \mathrm{End}(J_X) \longrightarrow \mathrm{End}(\Omega(X)).$$

To determine whether ϕ is an isogeny, we compute $D_X(\phi^\dagger\phi) = D_{X,Y}(\phi)D_{Y,X}(\phi^\dagger)$ and check that the result is equal to mI_{g_X} for some integer $m \neq 0$. Given m, we can use Lemma 3.2 to partially determine the group structure of $\ker\phi$.

It is straightforward to compute $D_{X,Y}(\phi)$ when ϕ is induced by a correspondence of the form $C = V(y_1 - y_2, A(x_1, x_2)) \subset X \times Y$. We begin by fixing ordered bases

$$\Omega(X) = \left\langle d(x_1^i)/y_1 : 1 \leq i \leq g_X \right\rangle \quad \text{and} \quad \Omega(Y) = \left\langle d(x_2^i)/y_2 : 1 \leq i \leq g_Y \right\rangle$$

for $\Omega(X)$ and $\Omega(Y)$. Then $D_{X,Y}(\cdot)$ becomes a representation into $\mathrm{Mat}_{g_X \times g_Y}(K)$ (viewing elements of $\Omega(X)$ and $\Omega(Y)$ as row vectors, with matrices representing homomorphisms act by multiplication on the right.) Pulling back our basis of $\Omega(X)$ to $\Omega(C)$ (via the inclusion $K(X) \hookrightarrow K(C)$ induced by π_X) and then taking the trace from $\Omega(C)$ to $\Omega(Y)$ (with respect to the inclusion $K(Y) \hookrightarrow K(C)$ induced by π_Y), we have

$$\phi_*(d(x_1^i)/y_1) = \mathrm{Tr}^{\Omega(C)}_{\Omega(Y)}(d(x_1^i)/y_1) = dt_i/y_2,$$

where t_i is the trace from $K(C)$ to $K(Y)$ of x_1^i. To compute these traces, we rewrite $A(x_1, x_2)$ as a polynomial in x_1 over $K[x_2]$ (after possibly rescaling to ensure A is monic in x_1):

$$A(x_1, x_2) = x_1^d + \sum_{i=1}^{d} (-1)^i s_i(x_2) x_1^{d-i}.$$

The s_i are the i^{th} elementary symmetric polynomials in the roots of A viewed as a polynomial in x_1 over $K(x_2)$; each s_i is a polynomial in x_2 over K of degree at most i. The function t_i is by definition the i^{th} power sum symmetric function in these same roots, and so we can express the t_i in terms of the s_j using the standard Newton-Girard recurrences:

$$ks_k = \sum_{i=1}^{k} (-1)^{i-1} s_{k-i} t_i.$$

Since each s_i has degree at most i, it follows that each of the trace functions t_i has degree at most i. We can therefore write

$$d(t_i)/y_2 = \sum_{j=1}^{i} t_{i,j} d(x_2^j)/y_2$$

with coefficients $t_{i,j}$ in K; these coefficients are precisely the entries of $D_{X,Y}(\phi)$ (with $t_{i,j} = 0$ for $j > i$).

We noted above that if $\phi : J_X \to J_Y$ is a homomorphism induced by a correspondence on $X \times Y$, then we obtain the Rosati dual $\phi^\dagger : J_Y \to J_X$ by simply exchanging X and Y. We may therefore compute $D_{Y,X}(\phi^\dagger)$ in exactly the same way we computed $D_{X,Y}(\phi)$, expressing the differentials $\phi^\dagger_*(d(x_2^i)/y_2) = \mathrm{Tr}^{\Omega(C)}_{\Omega(X)}(d(x_2^i)/y_2)$ as linear combinations of the $d(x_1^j)/y_1$.

If $\phi^\dagger \circ \phi = [m]_{J_X}$, then Lemma 3.2 allows us to determine the structure of $\ker\phi$ when m is squarefree. But in §6 we will encounter $m = 2$, 3, 4, and 8; we will therefore need another technique to handle $m = 4$ and $m = 8$.

Lemma 3.3. *Let $\phi : J_X \to J_Y$ be an isogeny over a field of characteristic not 2, such that $\phi^\dagger\phi = [m]_X$ with $m = 4$ or 8, and let ν be the $(\mathbb{Z}/2\mathbb{Z})$-rank of* $\ker\phi \cap J_X[2]$.

1. *If $m = 4$, then* $\ker\phi \cong (\mathbb{Z}/4\mathbb{Z})^{2g_X-\nu} \times (\mathbb{Z}/2\mathbb{Z})^{2(\nu-g_X)}$.
2. *If $m = 8$, then* $\ker\phi \cong (\mathbb{Z}/8\mathbb{Z})^{2g_X-\nu} \times (\mathbb{Z}/4\mathbb{Z})^{\nu-g_X} \times (\mathbb{Z}/4\mathbb{Z})^{\nu-g_X}$.

Proof. The result follows directly from Lemma 3.2. □

To apply Lemma 3.3, we need to compute the $(\mathbb{Z}/2\mathbb{Z})$-rank ν of $\ker\phi \cap J_X[2]$.

Lemma 3.4. *Let* $f(x) = \prod_{i=1}^{d}(x-\gamma_i)$ *and* $g(x) = \prod_{i=1}^{d}(x-\delta_i)$ *be polynomials of degree* $d > 2$ *over a field of characteristic not 2 such that* $f(x_1) - g(x_2)$ *has a nontrivial factor* $A(x_1, x_2)$*. Let* $X : y_1^2 = f(x_1)$ *and* $Y : y_2^2 = g(x_2)$ *be hyperelliptic curves, and* $\phi : J_X \to J_Y$ *the homomorphism induced by the correspondence* $V(y_1 - y_2, A(x_1, x_2))$ *on* $X \times Y$*. The* $(\mathbb{Z}/2\mathbb{Z})$*-rank of* $\ker\phi \cap J_X[2]$ *is given by*

$$\mathrm{rank}_{(\mathbb{Z}/2\mathbb{Z})}(\ker\phi \cap J_X[2]) = \dim(\ker M),$$

where M *is the* $2g_X \times 2g_Y$ *matrix over* $\mathbb{F}_2$ *with* i,j*-th entry* $\nu_{i,j} + \nu_{i,2g_Y+1} \pmod{2}$*, where* $\nu_{i,j}$ *denotes the multiplicity of* $(x_2 - \delta_j)$ *as factor of* $A(\gamma_i, x_2)$ *for* $1 \le i, j \le d$*.*

Proof. For each $1 \le i \le d$, we let w_i be the point $(\gamma_i, 0)$ on X and let w_i' be the point $(\delta_i, 0)$ on Y. If d is odd (so $d = 2g_X + 1 = 2g_Y + 1$), then we let w_{2g_X+2} (resp. w'_{2g_Y+2}) be the unique point at infinity on X (resp. Y), and we set $\nu_{i,2g_Y+2} := 0$ for $1 \le i \le 2g_X$. The sets $\{w_i : 1 \le i \le 2g_X + 2\}$ and $\{w_i' : 1 \le i \le 2g_X + 2\}$ are then the sets of Weierstrass points of X and Y, respectively. It is well-known that $J_X[2]$ (resp. $J_Y[2]$) is generated by differences of Weierstrass points of X (resp. Y), subject to the relations

$$\begin{aligned}
[(w_{2g_X+1}) - (w_{2g_X+2})] &= \textstyle\sum_{i=1}^{2g_X}[(w_i) - (w_{2g_X+2})] \quad \text{and} \\
[(w'_{2g_Y+1}) - (w'_{2g_Y+2})] &= \textstyle\sum_{i=1}^{2g_Y}[(w'_i) - (w'_{2g_Y+2})].
\end{aligned}$$

We therefore fix explicit bases for the 2-torsion:

$$J_X[2] = \langle[(w_i) - (w_{2g_X+2})]\rangle_{i=1}^{2g_X} \quad \text{and} \quad J_Y[2] = \left\langle[(w'_i) - (w'_{2g_Y+2})]\right\rangle_{i=1}^{2g_Y}.$$

Since ϕ restricts to a homomorphism $\phi|_2 : J_X[2] \to J_Y[2]$, we have a representation

$$T_2(\cdot) : \mathrm{Hom}(J_X, J_Y) \longrightarrow \mathrm{Hom}(J_X[2], J_Y[2]) \cong \mathrm{Mat}_{2g_X \times 2g_Y}(\mathbb{F}_2)$$

(where the isomorphism is determined by our choice of bases.) The $(\mathbb{Z}/2\mathbb{Z})$-rank of $\ker\phi \cap J_X[2] = \ker\phi|_2$ is then equal to the nullity of the matrix $T_2(\phi)$. The entries $t_{i,j}$ of $T_2(\phi)$ are determined by the relations

$$\phi([(w_i) - (w_{2g_X+2})]) = \sum_{j=1}^{2g_Y} t_{i,j}[(w'_j) - (w'_{2g_Y+2})]$$

(this is well-defined, since the $t_{i,j}$ are elements of $\mathbb{Z}/2\mathbb{Z}$). Explicitly computing the images of the basis elements, we find

$$\begin{aligned}
\phi([(w_i) - (w_{2g_X+2})]) &= \textstyle\sum_{j=1}^{2g_Y+1}(\nu_{i,j} - \nu_{i,2g_Y+2})[(w'_i) - (w'_{2g_Y+2})] \\
&= \left(\textstyle\sum_{j=1}^{2g_Y}(\nu_{i,j} - \nu_{i,2g_Y+2})[(w'_i) - (w'_{2g_Y+2})]\right) \\
&\quad + (\nu_{i,2g_Y+1} - \nu_{i,2g_Y+2})\left(\textstyle\sum_{j=1}^{2g_Y}[(w'_i) - (w'_{2g+2})]\right) \\
&= \textstyle\sum_{j=1}^{2g_Y}(\nu_{i,j} + \nu_{i,2g_Y+1} - 2\nu_{i,2g_Y+2})[(w'_i) - (w'_{2g_Y+2})] \\
&= \textstyle\sum_{j=1}^{2g_Y}(\nu_{i,j} + \nu_{i,2g_Y+1})[(w'_i) - (w'_{2g_Y+2})],
\end{aligned}$$

so $t_{i,j} \equiv \nu_{i,j} + \nu_{i,2g+1} \pmod{2}$ for $1 \le j \le 2g_Y$ and $1 \le i \le 2g_X$. Hence $M = T_2(\phi)$, and the result follows. □

Remark 3.1. In practice, computing the matrix M of Lemma 3.4 can be difficult if the roots of f and g are not all defined over a low-degree extension of the ground field. In our examples, we will be free to choose (reductions of) X and Y in such a way that all of the roots of f and g lie in a small finite field.

4. Pairs of polynomials

In order to use the construction of §2 to produce examples of explicit isogenies, we need a source of pairs of polynomials (f, g) such that $f(x_1) - g(x_2)$ is reducible. We will use the explicit classification of such pairs over $\mathbb{C}$ due to Cassou–Noguès and Couveignes [5], which we summarize in Theorem 4.1. This classification is restricted to indecomposable polynomials (in the sense of Definition 4.2), and classifies pairs up to an equivalence relation described in Definition 4.1.

Definition 4.1. We say that polynomials f_1 and f_2 over k are *linear translates* if there exist a and b in $\overline{k}$, with $a \neq 0$, such that $f_1(x) = f_2(ax + b)$. We say pairs (f_1, g_1) and (f_2, g_2) of polynomials are *equivalent* if there exists $c \neq 0$ and d in $\overline{k}$ such that f_1 and cf_2+d are linear translates and g_1 and cg_2+d are linear translates.

The "equivalence" of Definition 4.1 is indeed an equivalence relation on pairs of polynomials. Further, if $\mathcal{S}$ is an equivalence class, then either $f(x_1) - g(x_2)$ is $\overline{k}$-reducible for each (f, g) in $\mathcal{S}$ or $f(x_1) - g(x_2)$ is $\overline{k}$-irreducible for each (f, g) in $\mathcal{S}$.

Definition 4.2. A polynomial f is *decomposable* if $f(x) = f_1(f_2(x))$ for some polynomials f_1 and f_2 of degree at least 2, and *indecomposable* otherwise.

Theorem 4.1 (Cassou–Noguès and Couveignes [5])**.** *Let (f, g) be a pair of indecomposable polynomials of degree at least 3 over $\mathbb{C}$, and let σ denote complex conjugation. Assume the classification of finite simple groups.*

If f and g are linear translates, then $f(x_1) - g(x_2)$ is divisible by $x_1 - x_2$, and $(f(x_1) - g(x_2))/(x_1 - x_2)$ is reducible if and only if (f, g) is equivalent to either

1. *the pair (x^n, x^n) for some prime n, or*
2. *the pair $(D_n(x), D_n(x))$ for some prime n, where $D_n(x)$ is defined in Example 4.2.*

If f and g are not linear translates, then $f(x_1) - g(x_2)$ is reducible if and only if (f, g) is equivalent to one of the following (possibly after exchanging f and g):

3. *a pair in the one-parameter family (f_7, f_7^σ) defined in Example 4.3, or*
4. *the pair (f_{11}, f_{11}^σ) defined in Example 4.4, or*
5. *a pair in the one-parameter family (f_{13}, f_{13}^σ) defined in Example 4.5, or*
6. *a pair in the one-parameter family $(f_{15}, -f_{15}^\sigma)$ defined in Example 4.6, or*
7. *the pair (f_{21}, f_{21}^σ) defined in Example 4.7, or*
8. *the pair (f_{31}, f_{31}^σ) defined in Example 4.8.*

Example 4.1 (Cyclic polynomials)**.** The difference $x_1^n - x_2^n$ factors as

$$x_1^n - x_2^n = \prod_{e=0}^{n-1} (x_1 - \zeta_n^e x_2).$$

Example 4.2 (Dickson polynomials)**.** For each $n \geq 1$, we let $D_n(x) = D_n(x, 1)$ denote the n^{th} Dickson polynomial of the first kind with parameter 1: that is, the unique polynomial of degree n such that $D_n(x+x^{-1}, 1) = x^n+x^{-n}$. In characteristic zero we have $D_n(x) = 2T_n(x/2)$, where T_n is the classical Chebyshev polynomial of degree n. (See [20] for further details.) We have a nontrivial factorization

$$D_n(x_1) - D_n(x_2) = (x_1 - x_2) \prod_{i=1}^{(n-1)/2} A_{n,i}(x_1, x_2)$$

(see [20, Theorem 3.12]), where

$$A_{n,i}(x_1, x_2) := x_1^2 + x_2^2 - (\zeta_n^i + \zeta_n^{-i})x_1x_2 + (\zeta_n^i - \zeta_n^{-i}).$$

Example 4.3 (Polynomials of degree 7)**.** Let α_7 be an element of $\overline{\mathbb{Q}}$ satisfying

$$\alpha_7^2 + \alpha_7 + 2 = 0,$$

The involution $\sigma : \alpha_7 \mapsto 2/\alpha_7$ generates $\mathrm{Gal}(\mathbb{Q}(\alpha_7)/\mathbb{Q})$. Note that $\mathbb{Q}(\alpha_7) = \mathbb{Q}(\sqrt{-7})$ is a quadratic imaginary field, and σ acts as complex conjugation.

Let f_7 be the polynomial of degree 7 over $\mathbb{Q}(\alpha_7)[t]$ defined by

$$\begin{aligned} f_7(x) := {} & \tfrac{1}{7}x^7 - \alpha_7 t x^5 - \alpha_7 t x^4 - (2\alpha_7 + 5)t^2x^3 - (4\alpha_7 + 6)t^2x^2 \\ & + ((3\alpha_7 - 2)t^3 - (\alpha_7 + 3)t^2)x + \alpha_7 t^3. \end{aligned}$$

(Our f_7 is the polynomial of [5, §5.1] with $a_2 = \alpha_7$.) We have a nontrivial factorization $f_7(x_1) - f_7^\sigma(x_2) = A_7(x_1, x_2)B_7(x_1, x_2)$, where

$$A_7 = x_1^3 - x_2^3 - \alpha_7^\sigma x_1^2 x_2 + \alpha_7 x_1 x_2^2 + (3 - 2\alpha_7^\sigma)t x_1 - (3 - 2\alpha_7)t x_2 + (\alpha_7 - \alpha_7^\sigma)t;$$

note that $A_7(x_2, x_1) = -A_7(x_1, x_2)^\sigma$. Both A_7 and B_7 are absolutely irreducible.

Example 4.4 (Polynomials of degree 11)**.** Let α_{11} be an element of $\overline{\mathbb{Q}}$ satisfying

$$\alpha_{11}^2 + \alpha_{11} + 3 = 0;$$

the involution $\sigma : \alpha_{11} \mapsto 3/\alpha_{11}$ generates $\mathrm{Gal}(\mathbb{Q}(\alpha_{11})/\mathbb{Q})$. Note that $\mathbb{Q}(\alpha_{11}) = \mathbb{Q}(\sqrt{-11})$ is an imaginary quadratic field, and σ acts as complex conjugation.

Let f_{11} be the polynomial of degree 11 over $\mathbb{Q}(\alpha_{11})$ defined by

$$\begin{aligned} f_{11}(x) := {} & \tfrac{1}{11}x^{11} + \alpha_{11}x^9 + 2x^8 - 3(\alpha_{11} + 4)x^7 + 16\alpha_{11}x^6 \\ & - 3(7\alpha_{11} - 5)x^5 - 30(\alpha_{11} + 4)x^4 + 63(\alpha_{11} + 1)x^3 \\ & - 20(5\alpha_{11} - 1)x^2 - 3(8\alpha_{11} + 47)x + 18\alpha_{11}. \end{aligned}$$

(Our f_{11} is the polynomial of [5, §5.2] with $a_2 = \alpha_{11}^\sigma$.) We have a nontrivial factorization $f_{11}(x_1) - f_{11}^\sigma(x_2) = A_{11}(x_1, x_2)B_{11}(x_1, x_2)$, where

$$\begin{aligned} A_{11}(x_1, x_2) = {} & x_1^5 - \alpha_{11}x_1^4x_2 - x_1^3x_2^2 + (4\alpha_{11} + 2)x_1^3 + x_1^2x_2^3 + (\alpha_{11} + 6)x_1^2x_2 \\ & - (2\alpha_{11} - 10)x_1^2 - (\alpha_{11} + 1)x_1x_2^4 + (\alpha_{11} - 5)x_1x_2^2 \\ & - (12\alpha_{11} + 6)x_1x_2 + (8\alpha_{11} - 7)x_1 - x_2^5 + (4\alpha_{11} + 2)x_2^3 \\ & - (2\alpha_{11} + 12)x_2^2 + (8\alpha_{11} + 15)x_2 + 12\alpha_{11} + 6; \end{aligned}$$

note that $A_{11}(x_2, x_1) = -A_{11}^\sigma(x_1, x_2)$. Both A_{11} and B_{11} are absolutely irreducible.

Example 4.5 (Polynomials of degree 13)**.** Let β_{13} and α_{13} be elements of $\overline{\mathbb{Q}}$ satisfying

$$\beta_{13}^2 - 5\beta_{13} + 3 = 0 \quad \text{and} \quad \alpha_{13}^2 + (\beta_{13} - 2)\alpha_{13} + \beta_{13} = 0.$$

The involution $\sigma : \alpha_{13} \mapsto \beta_{13}/\alpha_{13}$ generates $\mathrm{Gal}(\mathbb{Q}(\alpha_{13})/\mathbb{Q}(\beta_{13}))$. Observe that $\mathbb{Q}(\beta_{13}) = \mathbb{Q}(\sqrt{13})$ is a real quadratic field, and $\mathbb{Q}(\alpha_{13}) = \mathbb{Q}(\sqrt{-3\sqrt{13} + 1})$ is an imaginary quadratic extension of $\mathbb{Q}(\beta_{13})$; so $\mathbb{Q}(\alpha_{13})$ is a CM-field, and σ acts as complex conjugation.

Let f_{13} be the polynomial of degree 13 over $\mathbb{Q}(\alpha_{13})[t]$ defined in Table 1:

$$\begin{aligned} f_{13}(x) = {} & \tfrac{1}{13}x^{13} + ((9\beta_{13} - 39)\alpha_{13} - 6\beta_{13} + 24)tx^{11} \\ & + ((9\beta_{13} - 39)\alpha_{13} - 12\beta_{13} + 51)tx^{10} + \cdots \end{aligned}$$

(note f_{13} is the polynomial of [5, §5.3] with $a_1 = \alpha_{13}$). We have a nontrivial factorization $f_{13}(x_1) - f_{13}^\sigma(x_2) = A_{13}(x_1, x_2)B_{13}(x_1, x_2)$, where

$$\begin{aligned} A_{13}(x_1, x_2) = {} & x_1^4 + x_2^4 + (\beta_{13} - 3)x_1^2x_2^2 - 9(3\beta_{13} - 14)tx_1x_2 + 12(47\beta_{13} - 202)t^2 \\ & - ((\beta_{13} - 4)\alpha_{13} + 2)x_1^3x_2 + ((\beta_{13} - 4)\alpha_{13} - \beta_{13} + 3)x_1x_2^3 \\ & + 3((17\beta_{13} - 73)\alpha_{13} - 12\beta_{13} + 50)tx_1^2 \\ & - 3((17\beta_{13} - 73)\alpha_{13} - 10\beta_{13} + 45)tx_2^2 \\ & + 3((5\beta_{13} - 22)\alpha_{13} - 9\beta_{13} + 38)tx_1 \\ & - 3((5\beta_{13} - 22)\alpha_{13} + 2\beta_{13} - 9)tx_2; \end{aligned}$$

note that $A_{13}(x_2, x_1) = A_{13}(x_1, x_2)^\sigma$. Both A_{13} and B_{13} are absolutely irreducible.

Table 1. Coefficients of the polynomial f_{13} (from Example 4.5)

d	Coefficient of x^d in f_{13}

0	$((-48359916\beta_{13}+208081872)\alpha_{13}-48359916\beta_{13})t^6$ $+((-13260672\beta_{13}+57057696)\alpha_{13}-13260672\beta_{13})t^5$

Example 4.6 (Polynomials of degree 15)**.** Let α_{15} be an element of $\overline{\mathbb{Q}}$ satisfying

$$\alpha_{15}^2-\alpha_{15}+4=0.$$

The involution $\sigma : \alpha_{15} \mapsto 4/\alpha_{15}$ generates $\operatorname{Gal}(\mathbb{Q}(\alpha_{15})/\mathbb{Q})$. Observe that $\mathbb{Q}(\alpha_{15}) = \mathbb{Q}(\sqrt{-15})$ is an imaginary quadratic field, and σ acts as complex conjugation.

Let f_{15} be the polynomial of degree 15 over $\mathbb{Q}(\alpha_{15})[t]$ defined in Table 2:

$$f_{15}(x)=\tfrac{1}{15}x^{15}+(\alpha_{15}-1)tx^{13}+(\alpha_{15}+7)tx^{12}+\cdots$$

(our f_{15} is the polynomial of [5, §5.4] with $a_1 = \alpha_{15}$.) We have a nontrivial factorization $f_{15}(x_1)-(-f_{15}^{\sigma}(x_2)) = A_{15}(x_1,x_2)B_{15}(x_1,x_2)$, where

$$\begin{aligned}A_{15}(x_1,x_2) = x_1^7 &- (\alpha_{15}-1)x_1^6x_2 - 2x_1^5x_2^2 + (7\alpha_{15}-3)tx_1^5 + (\alpha_{15}+1)x_1^4x_2^3\\
&+ 22tx_1^4x_2 + (5\alpha_{15}+65)tx_1^4 - (\alpha_{15}-2)x_1^3x_2^4 - (10\alpha_{15}+2)tx_1^3x_2^2\\
&- (50\alpha_{15}-70)tx_1^3x_2 + (9\alpha_{15}-69)t^2x_1^3 - 2x_1^2x_2^5\\
&+ (10\alpha_{15}-12)tx_1^2x_2^3 - 90tx_1^2x_2^2 + (39\alpha_{15}+33)t^2x_1^2x_2\\
&+ (210\alpha_{15}-150)t^2x_1^2 + \alpha_{15}x_1x_2^6 + 22tx_1x_2^4 + (50\alpha_{15}+20)tx_1x_2^3\\
&- (39\alpha_{15}-72)t^2x_1x_2^2 + 450t^2x_1x_2\\
&- ((63\alpha_{15}+45)t^3 - (225\alpha_{15}+900)t^2)x_1 + x_2^7 - (7\alpha_{15}-4)tx_2^5\\
&- (5\alpha_{15}-70)tx_2^4 - (9\alpha_{15}+60)t^2x_2^3 - (210\alpha_{15}-60)t^2x_2^2\\
&+ ((63\alpha_{15}-108)t^3 - (225\alpha_{15}-1125)t^2)x_2 - 675t^3;\end{aligned}$$

note that $A_{15}(x_2,x_1) = A_{15}(x_1,x_2)^{\sigma}$. Both A_{15} and B_{15} are absolutely irreducible.

Example 4.7 (Polynomials of degree 21)**.** Let α_{21} be an element of $\overline{\mathbb{Q}}$ satisfying

$$\alpha_{21}^2-\alpha_{21}+2=0.$$

The involution $\sigma : \alpha_{21} \mapsto 2/\alpha_{21}$ generates $\operatorname{Gal}(\mathbb{Q}(\alpha_{21})/\mathbb{Q})$; note that $\mathbb{Q}(\alpha_{21}) = \mathbb{Q}(\sqrt{-7})$ is an imaginary quadratic field, and σ acts as complex conjugation.

TABLE 2. Coefficients of the polynomial f_{15} (from Example 4.6)

Let f_{21} be the polynomial of degree 21 over k defined in Table 3:

$$f_{21}(x) = x^{21} + (42\alpha_{21}+42)x^{19} + (84\alpha_{21}+84)x^{18} + \cdots$$

(note $f_{21}(x) = 2^{21}g(x/2)$, where g is the polynomial of [5, §5.5] with $a_1 = \alpha_{21}$.) We have a nontrivial factorization $f_{21}(x_1) - f_{21}^{\sigma}(x_2) = A_{21}(x_1,x_2)B_{21}(x_1,x_2)$, where

$$\begin{aligned} A_{21}(x_1,x_2) = x_1^5 &+ (\alpha_{21}+1)x_1^4x_2 + 2\alpha_{21}x_1^3x_2^2 + (10\alpha_{21}+18)x_1^3 \\ &+ (2\alpha_{21}-2)x_1^2x_2^3 + (32\alpha_{21}-8)x_1^2x_2 + (20\alpha_{21}+4)x_1^2 \\ &+ (\alpha_{21}-2)x_1x_2^4 + (32\alpha_{21}-24)x_1x_2^2 + (32\alpha_{21}-16)x_1x_2 \\ &+ (107\alpha_{21}+55)x_1 - x_2^5 + (10\alpha_{21}-28)x_2^3 + (20\alpha_{21}-24)x_2^2 \\ &+ (107\alpha_{21}-162)x_2 + 136\alpha_{21} - 68. \end{aligned}$$

Note that $A_{21}(x_1,x_2) = -A_{21}^{\sigma}(x_2,x_1)$. Both A_{21} and B_{21} are absolutely irreducible.

Example 4.8 (Polynomials of degree 31). Let α_{31} and β_{31} be elements of $\overline{\mathbb{Q}}$ satisfying

$$\beta_{31}^3 - 13\beta_{31}^2 + 46\beta_{31} - 32 = 0 \quad \text{and} \quad \alpha_{31}^2 - 1/2(\beta_{31}^2 - 7\beta_{31} + 4)\alpha_{31} + \beta_{31} = 0.$$

The involution $\sigma : \alpha_{31} \mapsto \beta_{31}/\alpha_{31}$ generates $\mathrm{Gal}(\mathbb{Q}(\alpha_{31}/\mathbb{Q}(\beta_{31}))$; note that $\mathbb{Q}(\beta_{31})$ is a totally real cubic field, and $\mathbb{Q}(\alpha_{31})$ is a totally imaginary quadratic extension of $\mathbb{Q}(\beta_{31})$; so $\mathbb{Q}(\alpha_{31})$ is a CM-field, and σ acts as complex conjugation.

Let f_{31} be the polynomial of degree 31 over k defined in Tables 4 and 5:

$$\begin{aligned} f_{31}(x) = \tfrac{1}{31}x^{31} &- (\tfrac{1}{4}(\beta_{31}^2 - 5\beta_{31} - 10)\alpha_{31} - (\beta_{31}^2 - 7\beta_{31} + 12))x^{29} \\ &- (\tfrac{1}{2}(\beta_{31}^2 - 5\beta_{31} - 10)\alpha_{31} - (2\beta_{31}^2 - 14\beta_{31} + 24))x^{28} + \cdots \end{aligned}$$

(note $f_{31}(x) = 2^{31}g(x/2)/31$, where g is the polynomial of [5, §5.6] with $a_1 = \alpha_{31}$). We have a nontrivial factorization $f_{31}(x_1) - f_{31}^{\sigma}(x_2) = A_{31}(x_1, x_2)B_{31}(x_1, x_2)$, where

$$\begin{aligned} A_{31}(x_1, x_2) = x_1^{15} &+ (\tfrac{1}{4}(\beta_{31}^2 - 9\beta_{31} + 14)\alpha_{31} - \beta_{31} + 4)x_1^{14}x_2 \\ &+ \cdots \\ &+ (\tfrac{1}{4}(\beta_{31}^2 - 9\beta_{31} + 14)\alpha_{31} + \tfrac{1}{2}(\beta_{31}^2 - 7\beta_{31} + 2))x_1x_2^{14} - x_2^{15} \end{aligned}$$

is a polynomial of total degree 15 satisfying $A_{31}(x_1, x_2) = -A_{31}^{\sigma}(x_2, x_1)$. Both A_{31} and B_{31} are absolutely irreducible.

If (f, g) and (f', g') are equivalent pairs of polynomials, and $(\mathcal{X}, \mathcal{Y})$ and $(\mathcal{X}', \mathcal{Y}')$ the families of pairs of curves associated to (f, g) and (f', g') by the linear or quadratic constructions of §2, then $(\mathcal{X}, \mathcal{Y})$ and $(\mathcal{X}', \mathcal{Y}')$ are isomorphic. Indeed, suppose $f'(x) = cf(a_1x + b_1) + d$ and $g'(x) = cg(a_2x + b_2) + d$ for some a_1, b_1, a_2, b_2, c, and d in k with c, a_1 and a_2 nonzero. The isomorphism $(\mathcal{X}, \mathcal{Y}) \to (\mathcal{X}', \mathcal{Y}')$ is defined by $(x_i, y_i) \mapsto (a_ix_1 + b_i, c^{1/2}y_i)$ and $s \mapsto (s + d)/c$ for the linear construction, and by $(x_i, y_i) \mapsto (a_ix_1 + b_i, cy_i)$ and $(s_1, s_2) \mapsto ((s_2 + 2d)/c, (s_2 + ds_1 + d^2)/c^2)$ for the quadratic construction.

(4) *For* $n = 7, 13, 15$, *the image of the family* $\mathcal{X} : y^2 = f_n(x)^2 + s_1 f_n(x) + s_2$ *in* $\mathcal{H}_{(n-1)}$ *is three-dimensional.*

Proof. We will show that only finitely many curves in each family $\mathcal{X}$ can be isomorphic to a given element of $\mathcal{X}$. This implies that intersection of $\mathcal{X}(\overline{\mathbb{Q}})$ with the isomorphism class of a curve X in $\mathcal{X}(\overline{\mathbb{Q}})$ is finite, and hence that the map from $\mathcal{X}(\overline{\mathbb{Q}})$ into the moduli space of hyperelliptic curves is finite. The dimension of the image of $\mathcal{X}$ in the moduli space is then equal to the number of parameters of $\mathcal{X}$.

Consider (1): if $X : y^2 = c_0x^n + c_1x^{n-1} + c_2x^{n-2} + \cdots + c_n$ is a hyperelliptic curve in the family $\mathcal{X}$, then the coefficients c_i satisfy conditions

$$\text{(A)}: c_0 = 1, \quad \text{(B)}: c_1 = 0, \quad \text{(C)}: c_2 \neq 0, \quad \text{and} \quad \text{(D)}: c_3 = \kappa_n c_2,$$

where $\kappa_{11} = 2/\alpha_{11}$, $\kappa_{21} = 2$, and $\kappa_{31} = 2$.

If $X' : (y')^2 = f_n(x') + s'$ is isomorphic to X, then there exists a birational map $\psi : X \to X'$ defined by

$$\psi : (x, y) \mapsto (x', y') = \left(\frac{\alpha x + \beta}{\gamma x + \delta}, \frac{\epsilon y}{(\gamma x + \delta)^{(n+1)/2}} \right)$$

with α, β, γ, δ, and ϵ in $\overline{\mathbb{Q}}$ sastisfying $\epsilon \neq 0$ and $\alpha\delta - \beta\gamma \neq 0$, and X' has a defining equation $X' : y^2 = \epsilon^{-2}(\gamma x + \delta)^{n+1}(f_n((\alpha x + \beta)/(x + \delta)) + s)$.

If $\gamma = 0$, then we may take $\delta = 1$, so $\psi(x, y) = (\alpha x + \beta, \epsilon y)$. If X' is in $\mathcal{X}$ then it satisfies (A), (B), (C), and (D). Condition (A) implies $\alpha^n = \epsilon^2$, while (B) forces $\beta = 0$. The coefficients of x^{n-2} and x^{n-3} in $f_n(\alpha x) + s$ are then $\alpha^{n-2}c_2$ and $\alpha^{n-3}c_3 = \alpha^{n-3}\kappa_n c_2$, whereupon (C) and (D) imply $\alpha = 1$, and hence $\epsilon = \pm 1$. We conclude that ψ must be either the identity map or the hyperelliptic involution, depending on the sign of ϵ; in either case, $X' = X$.

If $\gamma \neq 0$, then we may take $\gamma = 1$. For the hyperelliptic polynomial of X' to have degree n we must have $\delta = -\rho$, where ρ is one of the roots of $f_n(x) + s$. Conditions (A), (B), (C), and (D) then uniquely determine α, β, γ, and ϵ (up to sign) in terms of ρ and κ_n. Since there were only n possible choices of ρ, we find that there are only $2n$ possible choices for ψ, and only n modulo the hyperelliptic involution.

We have shown that there are only $n + 1$ possible defining equations for curves in $\mathcal{X}$ isomorphic to X (in fact, each corresponds to a choice of Weierstrass point of X). has a unique defining equation (since the coefficient of x^0 in the defining equation uniquely determines a point of the parameter space); hence there are at most $n + 1$ curves in $\mathcal{X}$ isomorphic to X.

The proof is identical for (2), though in this case we must restrict to the open subfamily of $\mathcal{X}$ where $t \neq 0$ (so that (B) holds), and take $\kappa_7 = 1$, $\kappa_{13} = -((2\beta_{13} - 9)\alpha_6 - \beta_{13} + 3)/3$, and $\kappa_{15} = -2\alpha_{15} + 1$. Again, each curve in $\mathcal{X}$ has a unique defining equation: the coefficients of x^0 and x^n uniquely determine a point of the parameter space.

The proof for (3) and (4) is similar, and we only sketch it here. This time the curves $X : y^2 = \sum_{i=0}^{2n} c_i x^{2n-i}$ in $\mathcal{X}$ (or the subfamily where $t = 0$ in (4)) satisfy

$$\begin{array}{lll} \text{(A')}: c_0 = 1, & \text{(B')}: c_1 = 0, & \text{(C')}: c_2 \neq 0, \\ \text{(D')}: c_3 = \kappa_n c_2, & \text{(E')}: c_4 \neq 0, & \text{(F')}: c_5 = \lambda_n c_4, \end{array}$$

with κ_n defined as above and

$$\begin{aligned} \lambda_7 &= \tfrac{1}{277}(44\alpha_7 + 502), \\ \lambda_{11} &= \tfrac{-1}{1049}(1444\alpha_{11} + 1292), \\ \lambda_{13} &= \tfrac{-1}{24470889}(32177912\beta_{13} - 144562170)\alpha_{13} - 14922610\beta_{13} + 44742102), \\ \lambda_{15} &= \tfrac{-1}{3061}(11624\alpha_{15} - 8242), \\ \lambda_{21} &= \tfrac{-1}{24889}(1872\alpha_2 121 - 98252), \quad \text{and} \\ \lambda_{31} &= \tfrac{1}{5572804315201}((-23763234474\beta_{31}^2 + 308913876190\beta_{31} - 904140145396)\alpha_{31} \\ &\qquad + (45939160324\beta_{31}^2 - 413033009792\beta_{31} + 22556391264028)). \end{aligned}$$

As before, the defining equation of any curve in $\mathcal{X}$ isomorphic to X is uniquely determined by (A'), (B'), (C'), (D'), (E'), (F'), and the choice of a root of $f_n(x)^2 + s_1 f_n(x) + s_2$. The curves in $\mathcal{X}$ have unique defining equations, since the coefficients of x^0 and x^n (and x^{2n-2} in (4)) uniquely determine the corresponding point of the parameter space. Hence there are at most $2n$ curves in $\mathcal{X}$ isomorphic to X. □

5. Explicit Complex and Real Multiplications

We now apply the methods of §2 and §3 to the factorizations in Examples 4.1 and 4.2. Most of the resulting families have already been investigated elsewhere, so we treat them only briefly here. Throughout this section n denotes an odd prime.

Example 5.1. The linear construction on (x^n, x^n) yields a family $(\mathcal{X}, \mathcal{X})$ of pairs of hyperelliptic curves of genus $(n-1)/2$, defined by $\mathcal{X} : y_i^2 = x_i^n + s$. The curves in $\mathcal{X}$ are all isomomorphic to the curve $X : y_i^2 = x_i^n + 1$ (via $(x_i, y_i) \mapsto (\sqrt[n]{s}x_i, \sqrt{s}y_i)$). The Jacobian J_X is absolutely simple by [23, Example 8.4.(1)]. The correspondence $C = V(y_1 - y_2, x_1 - \zeta_n^e x_2)$ on $X \times X$ induces an endomorphism ϕ of J_X. Clearly $d(x_1^i)/y_1 = \zeta_n^{ie} d(x_2^i)/y_2$ on C, so

$$D_{X,Y}(\phi) = \operatorname{diag}(\zeta_n^e, \zeta_n^{2e}, \ldots, \zeta_n^{(n-1)e/2}).$$

The factors $x_1 - \zeta_n^e x_2$ of $x_1^n - x_2^n$ therefore correspond to explicit generators for a subring of $\operatorname{End}(J_X)$ isomorphic to $\mathbb{Z}[\zeta_n]$.

Example 5.2. The quadratic construction on (x^n, x^n) yields a two-parameter family $(\mathcal{X} : y_1^2 = x_1^{2n} + s_1 x_1^n + s_2,\ \mathcal{X} : y_2^2 = x_2^{2n} + s_1 x_2^n + s_2)$ of pairs of hyperelliptic curves of genus $n-1$. Twisting by $(x_i, y_i) \mapsto (s_2^{1/2n} x_i, s_2^{1/2} y_i)$, we reduce to the one-parameter family $\mathcal{X}' : y^2 = x^{2n} + s_1 x^n + 1$ of [26, Remark after Proposition 3]. The family $\mathcal{X}'$ has an involution $\iota : (x, y) \mapsto (1/x, y/x^n)$ which is clearly not the hyperelliptic involution, so $\mathcal{J}_{\mathcal{X}'}$ is reducible. The correspondences $V\big(y_1 - y_2, x_2 - \zeta_n^i x_1\big)$ on $\mathcal{X}' \times_T \mathcal{X}'$ induce endomorphisms generating a subring of $\operatorname{End}(\mathcal{J}_{\mathcal{X}'})$ isomorphic to $\mathbb{Z}[\zeta_n]$, as in Example 5.1. The quotient of $\mathcal{X}'$ by $\langle \iota \rangle$ is a one-parameter family of curves of genus $(n-1)/2$ whose Jacobians have Real Multiplication by $\mathbb{Z}[\zeta_n + \zeta_n^{-1}]$.

Example 5.3. Let D_n and $A_{n,i}$ be defined as in Example 4.2. The linear construction on $(D_n(x), D_n(x))$ yields a one-parameter family

$$(\mathcal{X} : y_1^2 = D_n(x_1) + s,\ \mathcal{X} : y_2^2 = D_n(x_2) + s);$$

of pairs of hyperelliptic curves of genus $(n-1)/2$ over $\mathbb{Q}$. The family $\mathcal{X}$ is identical to the family $\mathcal{C}_t$ of [26, Theorem 1]. It is shown in [26] that the endomorphisms induced by $V(y_1 - y_2, A_{n,i}(x_1, x_2))$ for $1 \leq i \leq (n-1)/2$ generate a subring of $\operatorname{End}(\mathcal{J}_{\mathcal{X}})$ isomorphic to $\mathbb{Z}[\zeta_n + \zeta_n^{-1}]$ (while $V(y_1 - y_2, x_1 - x_2)$ clearly induces $[1]_{\mathcal{J}_{\mathcal{X}}}$). It is shown that $\mathcal{J}_{\mathcal{X}}$ is absolutely simple for $n > 5$ in [26, Corollary 6] and for $n = 5$ in [17, Remark 15]. The cases $n = 5$ and $n = 7$ of this construction appear as families of efficiently computable endomorphisms in [17].

Example 5.4. Applied to $(D_n(x), D_n(x))$, the quadratic construction yields a two-parameter family

$$(\mathcal{X} : y_1^2 = D_n(x_1)^2 + s_1 D_n(x_1) + s_2,\ \mathcal{X} : y_2^2 = D_n(x_2)^2 + s_1 D_n(x_2) + s_2)$$

of pairs of hyperelliptic curves of genus $n-1$. We have a nontrivial factorization

$$\begin{aligned} &(D_n(x_1)^2 + s_1 D_n(x_1)) - (D_n(x_2)^2 + s_1 D_n(x_2) \\ &= (D_n(x_1) - D_n(x_2))(D_n(x_1) + D_n(x_2) + s_1) \\ &= \big((x_1 - x_2) \textstyle\prod_{i=1}^{(n-1)/2} A_{n,i}(x_1, x_2)\big)\big((D_n(x_1) + D_n(x_2) + s_1)\big). \end{aligned}$$

The correspondences $V(y_1 - y_2, A_{n,i}(x_1, x_2))$ on $X \times_T Y$ induce endomorphisms ϕ_i of $\mathcal{J}_{\mathcal{X}}$ for $1 \leq i \leq (n-1)/2$; the diagonal correspondence $V(y_1 - y_2, x_1 - x_2)$ induces $[1]_{J_X}$. The matrix $D_{\mathcal{X},\mathcal{X}}(\phi_i)$ is an endomorphism of $\Omega(X)$. Since $D_{\mathcal{X},\mathcal{X}}(\phi_i)$ is lower-triangular, its characteristic polynomial (and hence that of ϕ_i) is

$$P(x) = \prod_{j=1}^{(n-1)} (x - t_{j,j}),$$

where $t_{j,j}$ is the j^{th} entry on the diagonal of $D_{\mathcal{X},\mathcal{X}}(\phi_i)$: that is, $t_{j,j}$ is the leading coefficient of the trace $t_j = \operatorname{Tr}_{\Omega(X)}^{\Omega(C_i)}(d(x_1^j)/y_1)$ written as a polynomial in x_2. We have

$$A_{n,i}(x_1, x_2) = x_1^2 - (\zeta_n^i + \zeta_n^{-i})x_2 \cdot x_1 + (x_2^2 + \zeta_n^i - \zeta_n^{-i}),$$

so

$$\begin{aligned}
t_1 &= (\zeta_n^i + \zeta_n^{-i})x_2,\\
t_2 &= (\zeta_n^{2i} + \zeta_n^{-2i})x_2^2 - 2(\zeta_n^i - \zeta_n^{-i}), \text{ and}\\
t_j &= (\zeta_n^i + \zeta_n^{-i})x_2 t_{j-1} - (x_2^2 + \zeta_n^i - \zeta_n^{-i})t_{j-2} \text{ for } j > 2;
\end{aligned}$$

in particular, the coefficients $t_{j,j}$ satisfy $t_{1,1} = \zeta_n^i + \zeta_n^{-i}$, $t_{2,2} = \zeta_n^{2i} + \zeta_n^{-2i}$, and

$$t_{j,j} = (\zeta_n^i + \zeta_n^{-i})t_{j-1,j-1} - t_{j-2,j-2} \quad \text{for } j > 2.$$

Solving the second-order linear recurrence, we find $t_{j,j} = \zeta_n^{ij} + \zeta_n^{-ij}$ for all $j > 0$, so

$$P(x) = \prod_{j=1}^{(n-1)} (x - (\zeta_n^{ij} + \zeta_n^{-ij})) = m(x)^2,$$

where m is the minimal polynomial of $\zeta_n + \zeta_n^{-1}$ over $\mathbb{Q}$; hence $m(\phi_i) = 0$. We conclude that ϕ_i generates an explicit subring of $\mathrm{End}(\mathcal{J}_{\mathcal{X}})$ isomorphic to $\mathbb{Z}[\zeta_n + \zeta_n^{-1}]$.

6. Families of explicit isogenies

We now apply the methods of §2 and §3 to the factorizations in Examples 4.3 through 4.8. The examples in this section form the proof of Theorem 1.1.

Example 6.1. Let f_7, A_7, α_7, and σ be as in Example 4.3. The linear construction on (f_7, f_7^σ) yields a two-parameter family

$$\big(\mathcal{X} : y_1^2 = f_7(x_1) + s,\ \mathcal{Y} : y_2^2 = f_7^\sigma(x_2) + s\big)$$

of pairs of hyperelliptic curves of genus 3 defined over $\mathbb{Q}(\alpha_7)$. Specializing $\mathcal{X}$ at $(s,t) = (1,0)$ we obtain the curve X of Example 5.1 with $n = 7$, where we noted that J_X was absolutely simple; hence the generic fibre of $\mathcal{J}_{\mathcal{X}}$ is absolutely simple.

The correspondence $V(y_1 - y_2, A_7(x_1, x_2))$ on $\mathcal{X} \times_T \mathcal{Y}$ induces a homomorphism $\phi : \mathcal{J}_{\mathcal{X}} \to \mathcal{J}_{\mathcal{Y}}$. We have

$$D_{X,Y}(\phi) = \begin{pmatrix} \alpha_7 & 0 & 0 \\ 0 & \alpha_7 & 0 \\ (\alpha_7^\sigma - \alpha_7)t & 0 & \alpha_7^\sigma \end{pmatrix},$$

and therefore

$$D_{X,Y}(\phi) D_{Y,X}(\phi^\dagger) = D_{X,Y}(\phi) D_{X,Y}(\phi)^\sigma = 2I_3,$$

so $\phi^\dagger \circ \phi = [2]_{\mathcal{J}_{\mathcal{X}}}$; hence $\ker\phi \cong (\mathbb{Z}/2\mathbb{Z})^3$ by Lemma 3.2. The image of $\mathcal{J}_{\mathcal{X}}$ in $\mathcal{A}_3$ is two-dimensional by Lemma 4.2 and Torelli's theorem. We conclude that ϕ is a two-dimensional family of $(\mathbb{Z}/2\mathbb{Z})^3$-isogenies of (generically) absolutely simple Jacobians, thus proving Theorem 1.1 for the first row of the table.

Remark 6.1. More generally, given a hyperelliptic curve X of genus 3 and a maximal 2-Weil isotropic subgroup S of $J_X[2]$, there exists a (possibly reducible) curve Y of genus 3 and a $(\mathbb{Z}/2\mathbb{Z})^3$-isogeny $\phi : J_X \to J_Y$ with kernel S (both Y and ϕ may be defined over a quadratic extension of the field of definition of S). In general, the curve Y is *not* hyperelliptic. An algorithm which computes equations for Y and ϕ in the case where S is generated by differences of Weierstrass points appears in [25] (it is possible to show, using techniques similar to those of Lemma 3.4, that the kernel of the isogeny of Example 6.1 is not such a subgroup). The case where X is non-hyperelliptic is treated in [19].

Example 6.2. Let f_7, A_7, α_7, and σ be as in Examples 4.3 and 6.1. The quadratic construction on (f_7, f_7^σ) yields a three-parameter family

$$\big(\mathcal{X} : y_1^2 = f_7(x_1)^2 + s_1 f_7(x_1) + s_2,\ \mathcal{Y} : y_2^2 = f_7^\sigma(x_2)^2 + s_1 f_7^\sigma(x_2) + s_2\big)$$

of pairs of hyperelliptic curves of genus 6 defined over $\mathbb{Q}(\alpha_7)$. Specializing $\mathcal{X}$ at $(s_1, s_2, t) = (1, 0, 1)$ and reducing modulo a prime of $\mathbb{Q}(\alpha_7)$ over 13, we obtain a curve $\overline{X}$ over $\mathbb{F}_{13^2}$. The Weil polynomial of $J_{\overline{X}}$ is irreducible, and corresponds to the Weil coefficients

$$w_1 = -16, w_2 = -46, w_3 = 3496, w_4 = -36993, w_5 = -464728, w_6 = 13747140.$$

Applying Lemma 3.1, we see that $J_{\overline{X}}$ is absolutely simple. Hence, the generic fibre of $\mathcal{J}_{\mathcal{X}}$ is absolutely simple.

The correspondence $V(y_1 - y_2, A_7(x_1, x_2))$ on $\mathcal{X} \times_T \mathcal{Y}$ induces a homomorphism $\phi : \mathcal{J}_{\mathcal{X}} \to \mathcal{J}_{\mathcal{Y}}$. We find that

$$D_{X,Y}(\phi) = \begin{pmatrix} \alpha_7 & 0 & 0 & 0 & 0 & 0 \\ 0 & \alpha_7 & 0 & 0 & 0 & 0 \\ -(2\alpha_7+1)t & 0 & \alpha_7^\sigma & 0 & 0 & 0 \\ -(\alpha_7+4)t & -2(\alpha_7+4)t & 0 & \alpha_7 & 0 & 0 \\ 7(\alpha_7+2)t^2 & -2(2\alpha_7+1)t & 3(\alpha_7^\sigma+4)t & 0 & \alpha_7^\sigma & 0 \\ 7(\alpha_7^\sigma+4)t^2 & -7(2\alpha_7-3)t^2 & 3(\alpha_7^\sigma+4)t & 4(2\alpha_7^\sigma+1)t & 0 & \alpha_7^\sigma \end{pmatrix}.$$

Since $D_{Y,X}(\phi^\dagger) = D_{X,Y}(\phi)^\sigma$, we have

$$D_{X,X}(\phi^\dagger\phi) = D_{X,Y}(\phi)D_{Y,X}(\phi^\dagger) = 2I_6,$$

so $\phi^\dagger \circ \phi = [2]_{\mathcal{J}_{\mathcal{X}}}$; hence $\ker\phi \cong (\mathbb{Z}/2\mathbb{Z})^6$ by Lemma 3.2. The image of $\mathcal{J}_{\mathcal{X}}$ in $\mathcal{A}_6$ is three-dimensional by Lemma 4.2 and Torelli's theorem. We conclude that ϕ is a three-dimensional family of $(\mathbb{Z}/2\mathbb{Z})^6$-isogenies of (generically) absolutely simple Jacobians, thus proving Theorem 1.1 for the third row of the table.

Example 6.3. Let f_{11}, A_{11}, α_{11}, and σ be as in Example 4.4. The linear construction on (f_{11}, f_{11}^σ), yields a one-parameter family

$$\left(\mathcal{X} : y_1^2 = f_{11}(x_1) + s,\ \mathcal{Y} : y_2^2 = f_{11}^\sigma(x_2) + s\right)$$

of pairs of hyperelliptic curves of genus 5 over $\mathbb{Q}(\alpha_{11})$. Specializing $\mathcal{X}$ at $s = 0$ and reducing modulo a prime of $\mathbb{Q}(\alpha_{11})$ over 7, we obtain a curve $\overline{X}$ over $\mathbb{F}_{49}$. The Weil polynomial of $J_{\overline{X}}$ is irreducible, and corresponds to the Weil coefficients

$$w_1 = 12,\ w_2 = 28,\ w_3 = -152,\ w_4 = 3652,\ w_5 = 53722\ .$$

Applying Lemma 3.1, we see that $J_{\overline{X}}$ is absolutely simple. Hence, the generic fibre of $\mathcal{J}_{\mathcal{X}}$ is absolutely simple.

The correspondence $V(A_{11}(x_1, x_2), y_1 - y_2)$ on $\mathcal{X} \times_T \mathcal{Y}$ induces a homomorphism $\phi : \mathcal{J}_{\mathcal{X}} \to \mathcal{J}_{\mathcal{Y}}$. We find that

$$D_{X,Y}(\phi) = \begin{pmatrix} \alpha_{11} & 0 & 0 & 0 & 0 \\ 0 & \alpha_{11}^\sigma & 0 & 0 & 0 \\ \alpha_{11} + 6 & 0 & \alpha_{11} & 0 & 0 \\ 0 & 0 & 0 & \alpha_{11} & 0 \\ -3(5\alpha_{11} - 3) & 4(2\alpha_{11} + 1) & 3(\alpha_{11} + 6) & 0 & \alpha_{11} \end{pmatrix}.$$

Since $D_{Y,X}(\phi^\dagger) = D_{X,Y}(\phi)^\sigma$, we have $D_X(\phi^\dagger\phi) = 3I_5$, so $\phi^\dagger \circ \phi = [3]_{\mathcal{J}_{\mathcal{X}}}$; hence $\ker\phi \cong (\mathbb{Z}/3\mathbb{Z})^5$ by Lemma 3.2. The image of $\mathcal{J}_{\mathcal{X}}$ in $\mathcal{A}_5$ is one-dimensional by Lemma 4.2 and Torelli's theorem. We conclude that ϕ is a one-dimensional family of $(\mathbb{Z}/3\mathbb{Z})^5$-isogenies of (generically) absolutely simple Jacobians, thus proving Theorem 1.1 for the second row of the table.

Example 6.4. Let f_{11}, A_{11}, α_{11}, and σ be as in Examples 4.4 and 6.3. The quadratic construction on (f_{11}, f_{11}^σ) yields a two-parameter family

$$\left(\mathcal{X} : y_1^2 = f_{11}(x_1)^2 + s_1 f_{11}(x_1) + s_2,\ \mathcal{Y} : y_2^2 = f_{11}^\sigma(x_2)^2 + s_1 f_{11}(x) + s_2\right)$$

of pairs of hyperelliptic curves of genus 10 defined over $\mathbb{Q}(\alpha_{11})$. Specializing $\mathcal{X}$ at $(s_1, s_2) = (1, 0)$ and reducing modulo a prime of $\mathbb{Q}(\alpha_{11})$ over 7, we obtain a curve $\overline{X}$ over $\mathbb{F}_{49}$. The Weil polynomial of $J_{\overline{X}}$ is irreducible, and corresponds to the Weil

TABLE 6. Weil polynomial coefficients for Example 6.4

i	w_i	i	w_i	i	w_i	i	w_i	i	w_i
1	0	2	−16	3	196	4	2024	5	2484
6	35208	7	127220	8	10074824	9	24089728	10	−169499466

coefficients listed in Table 6. Applying Lemma 3.1, we see that $J_{\overline{X}}$ is absolutely simple. Hence, the generic fibre of $\mathcal{J}_{\mathcal{X}}$ is absolutely simple.

The correspondence $V(A_{11}(x_1, x_2), y_1 - y_2)$ on $\mathcal{X} \times_T \mathcal{Y}$ induces a homomorphism $\phi : \mathcal{J}_{\mathcal{X}} \to \mathcal{J}_{\mathcal{Y}}$. The 10×10 matrix $D_{X,Y}(\phi)$ is lower-triangular, with diagonal entries

$$\alpha_{11},\ \alpha_{11}^{\sigma},\ \alpha_{11},\ \alpha_{11},\ \alpha_{11},\ \alpha_{11}^{\sigma},\ \alpha_{11}^{\sigma},\ \alpha_{11}^{\sigma},\ \alpha_{11},\ \alpha_{11}^{\sigma},$$

each of which is an element of norm 3 (we omit the other entries for lack of space). We therefore have

$$D_{X,Y}(\phi)D_{Y,X}(\phi^{\dagger}) = D_{X,Y}(\phi)D_{X,Y}(\phi)^{\sigma} = 3I_{10},$$

so $\phi^{\dagger}\phi = [3]_{\mathcal{X}}$; hence $\ker\phi \cong (\mathbb{Z}/3\mathbb{Z})^{10}$ by Lemma 3.2. The image of $\mathcal{J}_{\mathcal{X}}$ in $\mathcal{A}_{10}$ is two-dimensional by Lemma 4.2 and Torelli's theorem. We conclude that ϕ is a two-dimensional family of $(\mathbb{Z}/3\mathbb{Z})^{10}$-isogenies of (generically) absolutely simple Jacobians, thus proving Theorem 1.1 for the sixth row of the table.

Example 6.5. Let f_{13}, A_{13}, α_{13}, β_{13} and σ be as in Example 4.5. The linear construction on $(f_{13}, f_{13}^{\sigma})$ yields a two-parameter family

$$\big(\mathcal{X} : y_1^2 = f_{13}(x_1) + s,\ \mathcal{Y} : y_2^2 = f_{13}^{\sigma}(x_2) + s\big)$$

of pairs of hyperelliptic curves of genus 6. Specializing $\mathcal{X}$ at $(s, t) = (1, 0)$, we obtain the curve X of Example 5.1 with $n = 13$, which has an absolutely simple Jacobian; hence the generic fibre of $\mathcal{J}_{\mathcal{X}}$ is absolutely simple.

The correspondence $V(A_{13}(x_1, x_2), y_1 - y_2)$ on $\mathcal{X} \times_T \mathcal{Y}$ induces a homomorphism $\phi : \mathcal{J}_{\mathcal{X}} \to \mathcal{J}_{\mathcal{Y}}$. The 6×6 matrix $D_{X,Y}(\phi)$ is lower-triangular; if we set $e_1 := (\beta_{13} - 4)\alpha_{13} + 2$ and $e_2 := \alpha + 1$, then the diagonal entries of $D_{X,Y}(\phi)$ are

$$e_1,\ \ e_2,\ \ e_1,\ \ e_1^{\sigma},\ \ e_2,\ \ e_2,$$

each of which is an element of norm 3 in $\mathbb{Q}(\beta_{13})$. (we omit the other entries for lack of space). We therefore have

$$D_{X,Y}(\phi)D_{Y,X}(\phi^{\dagger}) = D_{X,Y}(\phi)D_{X,Y}(\phi) = 3I_6,$$

so $\phi^{\dagger} \circ \phi = [3]_{\mathcal{J}_{\mathcal{X}}}$; hence $\ker\phi \cong (\mathbb{Z}/3\mathbb{Z})^6$ by Lemma 3.2. The image of $\mathcal{J}_{\mathcal{X}}$ in $\mathcal{A}_6$ is one-dimensional by Lemma 4.2 and Torelli's theorem. We conclude that ϕ is a one-dimensional family of $(\mathbb{Z}/3\mathbb{Z})^6$-isogenies of (generically) absolutely simple Jacobians, thus proving Theorem 1.1 for the fourth row of the table.

Example 6.6. Let f_{13}, A_{13}, α_{13}, β_{13} and σ be as in Examples 4.5 and 6.5. The quadratic construction on $(f_{13}, f_{13}^{\sigma})$ yields a three-parameter family

$$\big(\mathcal{X} : y_1^2 = f_{13}(x_1)^2 + s_1 f_{13}(x_1) + s_2,\ \mathcal{Y} : y_2^2 = f_{13}^{\sigma}(x_2)^2 + s_1 f_{13}^{\sigma}(x_2) + s_2\big)$$

of pairs of hyperelliptic curves of genus 12 defined over $\mathbb{Q}(\alpha_{13})$. Specializing $\mathcal{X}$ at $(s_1, s_2, t) = (1, 1, 1)$ and reducing modulo a prime of $\mathbb{Q}(\alpha_{13})$ over 5, we obtain a curve $\overline{X}$ over $\mathbb{F}_{5^4}$. The Weil polynomial of $J_{\overline{X}}$ is irreducible, and corresponds to the Weil coefficients listed in Table 7. Applying Lemma 3.1, we see that $J_{\overline{X}}$ is absolutely simple. Hence, the generic fibre of $\mathcal{J}_{\mathcal{X}}$ is absolutely simple.

The correspondence $V(A_{13}(x_1, x_2), y_1 - y_2))$ on $\mathcal{X} \times_T \mathcal{Y}$ induces a homomorphism $\phi : \mathcal{J}_{\mathcal{X}} \to \mathcal{J}_{\mathcal{Y}}$. The 12×12 matrix $D_{X,Y}(\phi)$ is lower-triangular, with diagonal entries

$$e_1,\ \ e_2,\ \ e_1,\ \ e_1^{\sigma},\ \ e_2,\ \ e_2,\ \ e_2^{\sigma},\ \ e_2^{\sigma},\ \ e_1,\ \ e_1^{\sigma},\ \ e_2^{\sigma},\ \ e_1^{\sigma}$$

Table 7. Weil polynomial coefficients for Example 6.6

i	w_i	i	w_i	i	w_i	i	w_i
1	20	4	351295	7	67298212	10	-49877419547660
2	-230	5	1293764	8	137879604915	11	1975333453052116
3	-9232	9	-1707055263168	6	-204257742	12	119629530410659866

(with e_1 and e_2 defined as in Example 6.5), each of which is an element of norm 3 in $\mathbb{Q}(\beta_{13})$. We therefore have

$$D_{X,Y}(\phi)D_{Y,X}(\phi^\dagger) = D_{X,Y}(\phi)D_{X,Y}(\phi)^\sigma = 3I_{12},$$

so $\phi^\dagger\phi = [3]_{\mathcal{X}}$; hence $\ker\phi \cong (\mathbb{Z}/3\mathbb{Z})^{12}$ by Lemma 3.2. The image of $\mathcal{J_X}$ in $\mathcal{A}_{12}$ is three-dimensional by Lemma 4.2 and Torelli's theorem. We conclude that ϕ is a three-dimensional family of $(\mathbb{Z}/3\mathbb{Z})^{12}$-isogenies of (generically) absolutely simple Jacobians, thus proving Theorem 1.1 for the eighth row of the table.

Example 6.7. Let f_{15}, A_{15}, α_{15}, and σ be as in Example 4.6. The linear construction on $(f_{15}, -f_{15}^\sigma)$ yields a two-parameter family

$$\big(\mathcal{X} : y_1^2 = f_{15}(x_2) + s,\ \mathcal{Y} : y_2^2 = -f_{15}^\sigma(x_2) + s\big)$$

of pairs of hyperelliptic curves of genus 7 defined over $\mathbb{Q}(\alpha_{15})$. Specializing $\mathcal{X}$ at $(s,t) = (0,1)$ and reducing modulo a prime of $\mathbb{Q}(\alpha_{15})$ over 17, we obtain a curve $\overline{X}$ over $\mathbb{F}_{17}$. The Weil polynomial χ of $J_{\overline{X}}$ is irreducible, and corresponds to the Weil coefficients

$$w_1 = 0,\ w_2 = -4,\ w_3 = -30,\ w_4 = 158,\ w_5 = 972,\ w_6 = -2264,\ w_7 = -18434.$$

Applying Lemma 3.1, we see that $J_{\overline{X}}$ is absolutely simple. Hence, the generic fibre of $\mathcal{J_X}$ is absolutely simple.

The correspondence $V(A_{15}(x_1,x_2), y_1 - y_2)$ on $\mathcal{X}\times_T\mathcal{Y}$ induces a homomorphism $\phi : \mathcal{J_X} \to \mathcal{J_Y}$. The 7×7 matrix $D_{X,Y}(\phi)$ is lower-triangular with diagonal entries

$$\alpha_{15}^\sigma,\ \alpha_{15}^\sigma,\ -2,\ \alpha_{15}^\sigma,\ 2,\ 2,\ -\alpha_{15},$$

each of which is an element of norm 4 (we omit the other entries for lack of space). We therefore find

$$D_{X,Y}(\phi)D_{Y,X}(\phi^\dagger) = D_{X,Y}(\phi)D_{X,Y}(\phi)^\sigma = 4I_7,$$

so $\phi^\dagger \circ \phi = [4]_{\mathcal{J_X}}$. Specializing at $(s,t) = (1,0)$ and reducing modulo a prime over 31, we obtain curves $\overline{X} : \bar{y}_1^2 = \bar{x}_1^{15} + 1$ and $\overline{Y} : \bar{y}_2^2 = -\bar{x}_2^{15} + 1$, together with an isogeny $\overline{\phi} : J_{\overline{X}} \to J_{\overline{Y}}$ induced by $V\big(\overline{A}(\bar{x}_1,\bar{x}_2), \bar{y}_1 - \bar{y}_2\big) \subset \overline{X}\times\overline{Y}$, where

$$\overline{A} = \bar{x}_1^7 + 14\bar{x}_1^6\bar{x}_2 - 2\bar{x}_1^5\bar{x}_2^2 + 19\bar{x}_1^4\bar{x}_2^3 + 15\bar{x}_1^3\bar{x}_2^4 - 2\bar{x}_1^2\bar{x}_2^5 + 18\bar{x}_1\bar{x}_2^6 + \bar{x}_2^7.$$

The polynomials $x_1^{15} + 1$ and $-x_2^{15} + 1$ both split completely over $\mathbb{F}_{31}$. Applying Lemmas 3.4 and 3.3, we see that $\ker\overline{\phi} \cong (\mathbb{Z}/4\mathbb{Z})^4\times(\mathbb{Z}/2\mathbb{Z})^6$. The image of $\mathcal{J_X}$ in $\mathcal{A}_7$ is two-dimensional by Lemma 4.2 and Torelli's theorem. We conclude that ϕ is a two-dimensional family of $(\mathbb{Z}/4\mathbb{Z})^4\times(\mathbb{Z}/2\mathbb{Z})^6$-isogenies of (generically) absolutely simple Jacobians, thus proving Theorem 1.1 for the fifth row of the table.

Example 6.8. Let f_{15}, A_{15}, α_{15}, and σ be as in Examples 4.6 and 6.7. The quadratic construction on $(f_{15}, -f_{15}^\sigma)$ yields a three-parameter family

$$\big(\mathcal{X} : y_1^2 = f_{15}(x_2)^2 + s_1 f_{15}(x_2) + s_2,\ \mathcal{Y} : y_2^2 = f_{15}^\sigma(x_2)^2 - s_1 f_{15}^\sigma(x_2) + s_2\big)$$

of pairs of hyperelliptic curves of genus 14 defined over $\mathbb{Q}(\alpha_{15})$. Specializing at $(s_1, s_2, t) = (1,1,1)$ and reducing modulo a prime of $\mathbb{Q}(\alpha_{15}$ over 17, we obtain a curve $\overline{X}$ over $\mathbb{F}_{17}$. The Weil polynomial χ of $J_{\overline{X}}$ is irreducible, and corresponds

TABLE 8. Weil polynomial coefficients for Example 6.8

w_i	4	36	272	1268	6492	28540	142200	453284	1065612	17399206

to the Weil coefficients listed in Table 8. Applying Lemma 3.1, we see that $J_{\overline{X}}$ is absolutely simple. Hence, the generic fibre of $\mathcal{J}_{\mathcal{X}}$ is absolutely simple.

The correspondence $V(A_{31}(x_1,x_2), y_1-y_2)$ on $\mathcal{X}\times_T\mathcal{Y}$ induces a homomorphism $\phi : \mathcal{J}_{\mathcal{X}} \to \mathcal{J}_{\mathcal{Y}}$. The 14×14 matrix $D_{X,Y}(\phi)$ is lower-triangular with diagonal entries

$$\alpha_{15}^{\sigma},\ \alpha_{15}^{\sigma},\ -2,\ \alpha_{15}^{\sigma},\ 2,\ 2,\ -\alpha_{15},\ \alpha_{15}^{\sigma},\ -2,\ -2,\ -\alpha_{15},\ 2,\ -\alpha_{15},\ \alpha_{15},$$

each of which is an element of norm 4 (we omit the other entries for lack of space.) We therefore find

$$D_{X,Y}(\phi)D_{Y,X}(\phi^{\dagger}) = D_{X,Y}(\phi)D_{X,Y}(\phi)^{\sigma} = 4I_{14},$$

so $\phi^{\dagger}\circ\phi = [4]_{\mathcal{J}_{\mathcal{X}}}$. Specializing at $(s_1, s_2, t) = (0, -1, 0)$ and reducing modulo a prime over 31, we obtain curves $\overline{X} : \bar{y}_1^2 = \bar{x}_1^{30} - 1$ and $\overline{Y} : \bar{y}_2^2 = \bar{x}_2^{30} - 1$, together with an isogeny $\overline{\phi} : J_{\overline{X}} \to J_{\overline{Y}}$ induced by $V\big(\overline{A}(\bar{x}_1,\bar{x}_2), \bar{y}_1 - \bar{y}_2\big) \subset \overline{X}\times\overline{Y}$, where

$$\overline{A} = \bar{x}_1^7 + 14\bar{x}_1^6\bar{x}_2 - 2\bar{x}_1^5\bar{x}_2^2 + 19\bar{x}_1^4\bar{x}_2^3 + 15\bar{x}_1^3\bar{x}_2^4 - 2\bar{x}_1^2\bar{x}_2^5 + 18\bar{x}_1\bar{x}_2^6 + \bar{x}_2^7.$$

The polynomial $x_i^{30} - 1$ splits completely over $\mathbb{F}_{31}$. Applying Lemmas 3.4 and 3.3, we see that $\ker\overline{\phi} \cong (\mathbb{Z}/4\mathbb{Z})^9 \times (\mathbb{Z}/2\mathbb{Z})^{10}$. The image of $\mathcal{J}_{\mathcal{X}}$ in $\mathcal{A}_{14}$ is three-dimensional by Lemma 4.2 and Torelli's theorem. We conclude that ϕ is a family of $(\mathbb{Z}/4\mathbb{Z})^9\times(\mathbb{Z}/2\mathbb{Z})^{10}$-isogenies of (generically) absolutely simple Jacobians, thus proving Theorem 1.1 for the ninth row of the table.

Example 6.9. Let f_{21}, A_{21}, α_{21}, and σ be as in Example 4.7. The linear construction on $(f_{21}, f_{21}^{\sigma})$ yields a one-parameter family

$$\big(\mathcal{X} : y_1^2 = f_{21}(x_1) + s,\ \mathcal{Y} : y_2^2 = f_{21}^{\sigma}(x_2) + s\big)$$

of pairs of hyperelliptic curves of genus 10 over $\mathbb{Q}(\alpha_{21})$. Specializing $\mathcal{X}$ at $s = 0$ and reducing modulo a prime of $\mathbb{Q}(\alpha_{21})$ over 5, we obtain a curve $\overline{X}$ over $\mathbb{F}_{25}$. The Weil polynomial χ of $J_{\overline{X}}$ is irreducible, and corresponds to the Weil coefficients listed in Table 9. Applying Lemma 3.1, we see that $J_{\overline{X}}$ is absolutely simple. Hence, the generic fibre of $\mathcal{J}_{\mathcal{X}}$ is absolutely simple.

The correspondence $V(A_{21}(x_1,x_2), y_1-y_2)$ on $\mathcal{X}\times_T\mathcal{Y}$ induces a homomorphism $\phi : \mathcal{J}_{\mathcal{X}} \to \mathcal{J}_{\mathcal{Y}}$. The 10×10 matrix $D_{X,Y}(\phi)$ is lower-triangular; if we set $e = (\alpha_{21}^{\sigma})^2$, then the diagonal entries of $D_{X,Y}(\phi)$ are

$$(\alpha_{21}^{\sigma})^2,\ (\alpha_{21}^{\sigma})^2,\ -(\alpha_{21}^{\sigma})^2,\ (\alpha_{21}^{\sigma})^2,\ \alpha_{21}^2,\ -(\alpha_{21}^{\sigma})^2,\ \alpha_{21}\alpha_{21}^{\sigma},\ (\alpha_{21}^{\sigma})^2,\ -\alpha_{21}^2,\ \alpha_{21}^2,$$

each of which is an element of norm 4 (we omit the other entries for lack of space). We therefore have

$$D_{X,Y}(\phi)D_{Y,X}(\phi^{\dagger}) = D_{X,Y}(\phi)D_{X,Y}(\phi)^{\sigma} = 4I_{10},$$

so $\phi^{\dagger}\circ\phi = [4]_{\mathcal{J}_{\mathcal{X}}}$. Specializing at $s = 425$ and reducing modulo a prime over 599, we obtain curves $\overline{X}$ and $\overline{Y}$ and an isogeny $\overline{\phi} : J_{\overline{X}} \to J_{\overline{Y}}$ over $\mathbb{F}_{599}$. Applying

Table 10. Weil polynomial coefficients for Example 6.10

4	403	8	105299	12	22091457	16	3592033583	20	476625334323

Lemmas 3.4 and 3.3, we find $\ker\overline{\phi}|_{J_{\overline{X}}[2]} \cong (\mathbb{Z}/2\mathbb{Z})^{11}$, so $\ker\phi \cong (\mathbb{Z}/4\mathbb{Z})^9\times(\mathbb{Z}/2\mathbb{Z})^2$. The image of $\mathcal{J}_{\mathcal{X}}$ in $\mathcal{A}_{10}$ is one-dimensional by Lemma 4.2 and Torelli's theorem. We conclude that ϕ is a one-dimensional family of $(\mathbb{Z}/4\mathbb{Z})^9\times(\mathbb{Z}/2\mathbb{Z})^2$-isogenies of (generically) absolutely simple Jacobians, thus proving Theorem 1.1 for the seventh row of the table.

Example 6.10. Let f_{21}, A_{21}, α_{21}, and σ be as in Examples 4.7 and 6.9. The quadratic construction on (f_{21}, f_{21}^σ) yields a two-parameter family

$$\big(\mathcal{X} : y_1^2 = f_{21}(x_1)^2 + s_1 f_{21}(x_1) + s_2,\ \mathcal{Y} : y_2^2 = f_{21}^\sigma(x_2)^2 + s_1 f_{21}^\sigma(x_2) + s_2\big)$$

of pairs of hyperelliptic curves of genus 10 defined over $\mathbb{Q}(\alpha_{21})$. Specializing $\mathcal{X}$ at $(s_1, s_2) = (1, 1)$ and reducing modulo a prime of $\mathbb{Q}(\alpha_{21})$ over 11, we obtain a curve $\overline{X}$ over $\mathbb{F}_{11}$. The Weil polynomial χ of $J_{\overline{X}}$ is irreducible, and corresponds to the Weil coefficients listed in Table 10. Applying Lemma 3.1, we see that $J_{\overline{X}}$ is absolutely simple. Hence, the generic fibre of $\mathcal{J}_{\mathcal{X}}$ is absolutely simple.

The correspondence $C = V(A_{21}(x_1, x_2), y_1 - y_2)$ on $\mathcal{X}_{20}\times_T\mathcal{Y}_{20}$ induces a homomorphism $\phi : \mathcal{J}_{\mathcal{X}} \to \mathcal{J}_{\mathcal{Y}}$. The 20×20 matrix $D_{X,Y}(\phi)$ is a lower-triangular; if we set $e := -(\alpha_{21} + 1)$, then the diagonal entries of $D_{X,Y}(\phi)$ are

$$(\alpha_{21}^\sigma)^2,\ (\alpha_{21}^\sigma)^2,\ -(\alpha_{21}^\sigma)^2,\ (\alpha_{21}^\sigma)^2,\ \alpha_{21}^2,\ -(\alpha_{21}^\sigma)^2,\ \alpha_{21}\alpha_{21}^\sigma,\ (\alpha_{21}^\sigma)^2,\ -\alpha_{21}^2,\ \alpha_{21}^2,$$
$$(\alpha_{21}^\sigma)^2, -(\alpha_{21}^\sigma)^2,\ \alpha_{21}^2,\ \alpha_{21}\alpha_{21}^\sigma,\ -\alpha_{21}^2,\ (\alpha_{21}^\sigma)^2,\ \alpha_{21}^2,\ -\alpha_{21}^2,\ \alpha_{21}^2,\ \alpha_{21}^2,$$

each of which is an element of norm 4 (we omit the other entries for lack of space). We therefore find

$$D_{X,Y}(\phi)D_{Y,X}(\phi^\dagger) = D_{X,Y}(\phi)D_{X,Y}(\phi)^\sigma = 4I_{20},$$

so $\phi^\dagger\circ\phi = [4]_{\mathcal{J}_{\mathcal{X}}}$. Specializing at $(s_1, s_2) = (1, 6)$ and reducing at a prime over 29, we obtain curves $\overline{X}$ and $\overline{Y}$ and an isogeny $\overline{\phi} : J_{\overline{X}} \to J_{\overline{Y}}$ over $\mathbb{F}_{29}$. Applying Lemmas 3.4 and 3.3, we see that $\ker\overline{\phi} \cong (\mathbb{Z}/4\mathbb{Z})^{19}\times(\mathbb{Z}/2\mathbb{Z})^2$. The image of $\mathcal{J}_{\mathcal{X}}$ in $\mathcal{A}_{20}$ is two-dimensional by Lemma 4.2 and Torelli's theorem. We conclude that ϕ is a two-dimensional family of $(\mathbb{Z}/4\mathbb{Z})^{19}\times(\mathbb{Z}/2\mathbb{Z})^2$-isogenies of (generically) absolutely simple Jacobians, thus proving Theorem 1.1 for the eleventh row of the table.

Example 6.11. Let f_{31}, A_{31}, α_{31}, β_{31}, and σ be as in Example 4.8. The linear construction on (f_{31}, f_{31}^σ) yields a one-parameter family

$$\big(\mathcal{X} : y_1^2 = f_{31}(x_1) + s,\ \mathcal{Y} : y_2^2 = f_{31}^\sigma(x_2) + s\big)$$

of pairs of hyperelliptic curves of genus 15 over $\mathbb{Q}(\alpha_{31})$. Specializing $\mathcal{X}$ at $s = 0$ and reducing modulo a prime of $\mathbb{Q}(\alpha_{31})$ over 5, we obtain a curve $\overline{X}$ over $\mathbb{F}_{5^3}$. The Weil polynomial of $J_{\overline{X}}$ is irreducible, and corresponds to the Weil coefficients listed in Table 11. The Jacobian $J_{\overline{X}}$ is absolutely simple by Lemma 3.1; hence the generic fibre of $\mathcal{J}_{\mathcal{X}}$ is absolutely simple.

The correspondence $C = V(A(x_1, x_2), y_1 - y_2)$ on $\mathcal{X}\times_T\mathcal{Y}$ induces a homomorphism $\phi : \mathcal{J}_{\mathcal{X}} \to \mathcal{J}_{\mathcal{Y}}$. The 15×15 matrix $D_{X,Y}(\phi)$ is lower-triangular; if we set $e_1 := -((\beta_{31}^2 - 9\beta_{31} + 14)\alpha_{31} + 4\beta_{31} - 16)/4$, $e_2 := -((\beta_{31} - 6)\alpha_{31} + \beta_{31}^2 - 8\beta_{31} + 8)/2$, and $e_3 := \alpha_{31} - \beta_{31} + 4$, then the diagonal entries of $D_{X,Y}(\phi)$ are

$$e_1,\ e_1,\ e_2,\ e_1,\ e_3,\ e_2,\ e_2^\sigma,\ e_1,\ e_3,\ e_3,\ e_3^\sigma,\ e_2,\ e_3^\sigma,\ e_2^\sigma,\ e_1^\sigma,$$

each of which is an element of norm 8 in $\mathbb{Q}(\beta_{31})$ (we omit the other entries for lack of space). We therefore find

$$D_{X,Y}(\phi)D_{Y,X}(\phi^\dagger) = D_{X,Y}(\phi)D_{X,Y}(\phi)^\sigma = 8I_{15},$$

so $\phi^\dagger \circ \phi = [8]_{\mathcal{J}_\mathcal{X}}$. Specializing at $s = 0$ and reducing modulo a prime over 47, we obtain curves $\overline{X}$ and $\overline{Y}$ and an isogeny $\overline{\phi} : J_{\overline{X}} \to J_{\overline{Y}}$ over $\mathbb{F}_{47}$. Applying Lemmas 3.4 and 3.3, we find $\ker \overline{\phi} \cong (\mathbb{Z}/8\mathbb{Z})^5 \times (\mathbb{Z}/4\mathbb{Z})^{10} \times (\mathbb{Z}/4\mathbb{Z})^{10}$. The image of $\mathcal{J}_\mathcal{X}$ in $\mathcal{A}_{15}$ is one-dimensional by Lemma 4.2 and Torelli's theorem. We conclude that ϕ is a one-dimensional family of $(\mathbb{Z}/8\mathbb{Z})^5 \times (\mathbb{Z}/4\mathbb{Z})^{10} \times (\mathbb{Z}/4\mathbb{Z})^{10}$-isogenies of (generically) absolutely simple Jacobians, thus proving Theorem 1.1 for the tenth row of the table.

Example 6.12. Let f_{31}, A_{31}, α_{31}, β_{31}, and σ be as in Examples 4.8 and 6.11. The quadratic construction on (f_{31}, f_{31}^σ) yields a two-parameter family

$$\big(\mathcal{X} : y_1^2 = f_{31}(x_1)^2 + s_1 f_{31}(x_1) + s_2,\ \mathcal{Y} : y_2^2 = f_{31}^\sigma(x_1)^2 + s_1 f_{31}^\sigma(x_2) + s_2\big)$$

of pairs of hyperelliptic curves of genus 30 defined over $\mathbb{Q}(\alpha_{31})$. Specializing $\mathcal{X}$ at $(s_1, s_2) = (1, 2)$ and reducing modulo a prime of $\mathbb{Q}(\alpha_{31})$ over 3, we obtain a curve $\overline{X}$ over $\mathbb{F}_{3^6}$. The Weil polynomial of $J_{\overline{X}}$ is irreducible, and corresponds to the Weil coefficients listed in Table 12. The Jacobian $J_{\overline{X}}$ is absolutely simple by Lemma 3.1; hence the generic fibre of $\mathcal{J}_\mathcal{X}$ is absolutely simple.

The correspondence $C = V(A_{31}(x_1, x_2), y_1 - y_2)$ on $\mathcal{X} \times_T \mathcal{Y}$ induces a homomorphism $\phi : \mathcal{J}_\mathcal{X} \to \mathcal{J}_\mathcal{Y}$. The 30×30 matrix $D_{X,Y}(\phi)$; is lower-triangular with diagonal entries

$$\begin{gathered} e_1,\ e_1,\ e_2,\ e_1,\ e_3,\ e_2,\ e_2^\sigma,\ e_1,\ e_3,\ e_3,\ e_3^\sigma,\ e_2,\ e_3^\sigma,\ e_2^\sigma,\ e_1^\sigma, \\ e_1,\ e_2,\ e_3,\ e_2^\sigma,\ e_3,\ e_3^\sigma,\ e_3^\sigma,\ e_1^\sigma,\ e_2,\ e_2^\sigma,\ e_3^\sigma,\ e_1^\sigma,\ e_2^\sigma,\ e_1^\sigma,\ e_1^\sigma \end{gathered}$$

(where e_1, e_2, and e_3 are defined as in Example 6.11), each of which is an element of norm 8 in $\mathbb{Q}(\beta_{31})$ (we omit the other entries for lack of space). We therefore have

$$D_{X,Y}(\phi)D_{Y,X}(\phi^\dagger) = D_{X,Y}(\phi)D_{X,Y}(\phi)^\sigma = 8I_{30},$$

so $\phi^\dagger \circ \phi = [8]_{\mathcal{J}_\mathcal{X}}$. Specializing at $(s_1, s_2) = (4, 9)$ and reducing modulo a prime over 47, we obtain curves $\overline{X}$ and $\overline{Y}$ and an isogeny $\overline{\phi} : J_{\overline{X}} \to J_{\overline{Y}}$ over $\mathbb{F}_{47}$. Applying Lemmas 3.4 and 3.3, we find $\ker \overline{\phi} \cong (\mathbb{Z}/8\mathbb{Z})^{11} \times (\mathbb{Z}/4\mathbb{Z})^{19} \times (\mathbb{Z}/4\mathbb{Z})^{19}$. The image of $\mathcal{J}_\mathcal{X}$ in $\mathcal{A}_{30}$ is two-dimensional by Lemma 4.2 and Torelli's theorem. We conclude that ϕ is a two-dimensional family of $(\mathbb{Z}/8\mathbb{Z})^{11} \times (\mathbb{Z}/4\mathbb{Z})^{19} \times (\mathbb{Z}/4\mathbb{Z})^{19}$-isogenies of (generically) absolutely simple Jacobians, thus proving Theorem 1.1 for the twelfth row of the table.
